Excerpt: . . . 13 MTP: . 4a Atomic Multicast Transport Protocol have less opportunity to react to missing data. Data can be missed for a variety of reasons. If constrained to the local net, the data lost due to corruption should be around one packet in 50, 000 r. Four orders of magnitude more packets are lost at receiving stations, including packet switch routers, than over physical links. The losses are usually the result of congestion and resource starvation at lower layers due to the processing of (nearly) back to back packets. One can only require that a receiving station be capable of receiving some number of back to back packets successfully, and that number must be at least greater than the window size. The probability of success can be made as high as needed by providing the receiver the opportunity to observe the data multiple times. At worst, the receiving station detects packet loss using timers. Such timers might have a granularity of more than two orders of magnitude greater than the maximum packet transmit time. As such, the worst case is much worse than detecting data loss due to gaps in sequence numbers. When the loss is detected, the response (a NAK) is transmitted and should be received at the producing process in less than two heartbeats after the data it references was transmitted. Again, it is the detection time that dominates, not the transmission of the NAK. NAKs are also subject to loss, but the probability of delivery can be made close to one by retransmitting. In order...
